BLM Sample Anchor Chart

Things we learned about ordering fractions

- Placing fractions on a number line is one way to think about ordering the fractions. The smaller the fraction, the farther to the left of the number line it will be; the larger the fraction, the farther to the right it will be.
- We can use a benchmark to place a fraction. Benchmarks include $\frac{1}{2}$ and 1 whole.
- When a fraction has the same numerator and denominator it is equivalent to one. E.g., $\frac{2}{2}=1$.
- As the numerator of a fraction gets closer to the denominator, the value of the fraction gets closer to the next whole number. E.g., $\frac{5}{7}$ is close to 1.
- Improper fractions are always greater than one. E.g., $\frac{19}{5}$ is greater than 1 and greater than 3.
- The greater the denominator the smaller the size of the parts of the whole are. E.g., the pieces of $\frac{15}{20}$ are smaller than the pieces of $\frac{1}{2}$.
- There are a number of different ways to represent a value using fractions. E.g., $1\frac{10}{20}=1\frac{1}{2}=\frac{3}{2}$.
- When using a number line to order a set of fractions, you first have to scale your number line. To do that: decide what the smallest and largest fractions are; make sure that your number line captures these numbers without a lot of length to spare; tick off benchmarks; label 0, 1, and any other whole numbers needed.
- You don't have to think about ordering the numbers in the sequence they are written in a list. It is strategic to order the easiest numbers first.
